

A Closed Character Formula for Symmetric Powers of Irreducible Representations

Stavros Kousidis[†]

Max Planck Institute for Mathematics, Vivatsgasse 7, 53111 Bonn, Germany

Abstract. We prove a closed character formula for the symmetric powers $S^N V(\lambda)$ of a fixed irreducible representation $V(\lambda)$ of a complex semi-simple Lie algebra \mathfrak{g} by means of partial fraction decomposition. The formula involves rational functions in rank of \mathfrak{g} many variables which are easier to determine than the weight multiplicities of $S^N V(\lambda)$ themselves. We compute those rational functions in some interesting cases. Furthermore, we introduce a residue-type generating function for the weight multiplicities of $S^N V(\lambda)$ and explain the connections between our character formula, vector partition functions and iterated partial fraction decomposition.

Résumé. Nous établissons une formule fermée pour le caractère de la puissance symétrique $S^N V(\lambda)$ d'une représentation irréductible $V(\lambda)$ d'une algèbre de Lie semi-simple complexe \mathfrak{g} , en utilisant des décompositions en fractions partielles. Cette formule exprime ce caractère en termes de fractions rationnelles en r variables, où r est le rang de \mathfrak{g} . Ces fractions sont plus faciles à déterminer que les multiplicités de la décomposition de $S^N V(\lambda)$ elles-mêmes. Nous calculons ces fonctions rationnelles dans quelques cas intéressants. Nous introduisons par ailleurs une fonction génératrice de type résidu pour les multiplicités de $S^N V(\lambda)$ et relierons notre formule aux fonctions de partitions vectorielles et aux décompositions itérées en fractions partielles.

Keywords: character, symmetric power, irreducible representation, generating function, residue, partial fraction decomposition, vector partition function

1 Notation

Let \mathfrak{g} be a complex semi-simple Lie algebra of rank r . Fix a Borel \mathfrak{b} and a Cartan subalgebra \mathfrak{h} in \mathfrak{g} and let $Q = \bigoplus_{i=1}^r \mathbb{Z}\alpha_i$ and $X = \bigoplus_{i=1}^r \mathbb{Z}\omega_i$ be the corresponding root and weight lattice spanned by the simple roots and fundamental weights respectively. Let $\alpha_1^\vee, \dots, \alpha_r^\vee$ be the simple coroots and W the Weyl group. An irreducible representation of \mathfrak{g} of highest weight $\lambda \in X^+$, where X^+ stands for all dominant weights, is denoted by $V(\lambda)$. Its character will be written as $\text{Char } V(\lambda)$ and it is well-known that it is an element of $\mathbb{Z}[X]$, the integral group ring associated to the weight lattice. Each generator $e^\mu \in \mathbb{Z}[X]$ yields a function on $\mathfrak{h}_{\mathbb{R}}$, the real span of the simple coroots, by $x \mapsto e^{\langle \mu, x \rangle}$. In this sense we have the associated Fourier series of the character of $V(\lambda)$ as a function of $\mathfrak{h}_{\mathbb{R}}$, i.e. $\text{Char } V(\lambda)(ix) = \sum_{\mu \in X} m_\mu e^{i\langle \mu, x \rangle}$. To simplify

[†]Supported by the Max Planck Institute for Mathematics and the Deutsche Forschungsgemeinschaft SFB/TR12 Symmetries and Universality in Mesoscopic Systems.

notation in what follows we define $q = e^{i\langle \cdot, x \rangle}$, i.e. $q^\mu = e^{i\langle \mu, x \rangle}$. Then, with respect to the coordinate system $\{\alpha_1^\vee, \dots, \alpha_r^\vee\}$ of $\mathfrak{h}_{\mathbb{R}}$ we have $q = (q_1, \dots, q_r)$ with $q_i = e^{i\langle \cdot, x_i \alpha_i^\vee \rangle}$ and for $\mu = c_1 \omega_1 + \dots + c_r \omega_r$

$$q^\mu = (q_1, \dots, q_r)^{(c_1, \dots, c_r)} = q_1^{c_1} \cdots q_r^{c_r} \in \mathbb{Z}[q_1^{\pm 1}, \dots, q_r^{\pm 1}]. \quad (1)$$

Note, whenever we write \mathbb{N} we mean the non-negative integers $\{0, 1, 2, \dots\}$.

2 Introduction and the Main Theorem

Let $m_{\lambda, N} : X \rightarrow \mathbb{N}$ be the weight multiplicity function for the N -th symmetric power of a fixed irreducible representation $V(\lambda)$ of \mathfrak{g} , i.e. $\text{Char } S^N V(\lambda) = \sum_{v \in X} m_{\lambda, N}(v) e^v \in \mathbb{Z}[X]$. Then, we have the combinatorial identity

$$m_{\lambda, N}(v) = \sum_{\substack{\{v_1, \dots, v_N\} \subset X \\ v_1 + \dots + v_N = v}} m_{\lambda, 1}(v_1) \cdots m_{\lambda, 1}(v_N). \quad (2)$$

In general it is a non-trivial problem to determine $m_{\lambda, N}$. That is, to establish a formula depending on N that counts the unordered pairs $\{v_1, \dots, v_N\}$ subject to the restriction $v_1 + \dots + v_N = v$.

We will instead identify the Fourier series associated to the character of $S^N V(\lambda)$ as an element of $\mathbb{C}(q_1, \dots, q_r)[X]$ (see section 1 for the notation). The key point is that this identification involves data (apart from terms in N) which is easier to determine than the function $m_{\lambda, N}$ and depends only on the fixed representation $V(\lambda)$. Starting point will be Molien's formula (see (Procesi, 2007, Chapter 9, §4.3)) which identifies the graded character of the symmetric algebra of $V(\lambda)$ as a product of geometric series. We will state this result here for a quick reference.

Lemma 2.1 (compare (Procesi, 2007, Chapter 9, §4.3)).

$$\text{Char } SV(\lambda) = \sum_{N=0}^{\infty} z^N \text{Char } S^N V(\lambda) = \prod_{v \in X} \frac{1}{(1 - e^v z)^{\dim V(\lambda)_v}} \quad (3)$$

Our main result will be Theorem 3.4 in Section 3. That is,

Theorem (Character formula). *Let \mathfrak{g} be a semi-simple complex Lie algebra of rank r and $V(\lambda)$ a fixed irreducible representation of \mathfrak{g} with weight space decomposition $V(\lambda) = \bigoplus_{v \in X} V(\lambda)_v$ and weight multiplicity function $m_\lambda : X \rightarrow \mathbb{N}$. Then, with $q = e^{i\langle \cdot, x \rangle} = (q_1, \dots, q_r)$ as above, we have*

$$\text{Char } S^N V(\lambda)(ix) = \sum_{v \in X} q^{Nv} \sum_{k=1}^{m_\lambda(v)} A_{v,k}(q) \cdot p_k(N) \in \mathbb{C}(q_1, \dots, q_r)[X] \quad (4)$$

with rational functions $A_{v,k}(q) \in \mathbb{C}(q_1, \dots, q_r)$ and polynomials $p_k(N) \in \mathbb{Q}[N]$ of degree $k-1$ given by

$$p_k(N) = \binom{N+k-1}{N}. \quad (5)$$

Furthermore, for a weight $\mu \in X$ and $l = 0, \dots, m_\lambda(\mu) - 1$ we have

$$A_{\mu, m_\lambda(\mu)-l}(q) = \frac{(-1)^l}{l! q^{l\mu}} \cdot \frac{d^l}{(dz)^l} \left[\prod_{v \in X \setminus \mu} \frac{1}{(1 - q^v z)^{m_\lambda(v)}} \right]_{z=q^{-\mu}}. \quad (6)$$

We will apply this theorem to prove character formulas in some interesting cases, involving in particular concrete expressions for the rational functions. To the authors' knowledge there is no formula of such type known so far although the derivation of the Main Theorem is based on simple observations⁽ⁱ⁾.

In Section 4, Proposition 4.1 we will prove an integral expression for the generating function associated to the weight multiplicity functions $m_{N,\lambda}$ (evaluated at a fixed weight $\mu \in X$) of the sequence of representations $S^N V(\lambda)$. Based on this identity and our Main Theorem above we will explain the nature of this generating function and in particular why it is of residue-type.

Section 5 will be a short sketch of the connections between the results of section 3, 4 and vector partition functions and iterated partial fraction decomposition (see e.g. Beck (2004) and Bliem (2009)).

Section 6 comments on an important continuation of the present discussion. That is, the character formula established in the Main Theorem can be split into individual parts belonging to the Weyl group orbits of dominant weights. The question is what can be expected from the iterated partial fraction decomposition of those individual terms. We illustrate a possible answer by an example. A detailed treatment will appear in the full version of this extended abstract.

3 A closed character formula for symmetric powers

We will derive a closed character formula for the representation $S^N V(\lambda)$ in terms of a basis of weight vectors of the irreducible representation $V(\lambda)$ with weight multiplicity function m_λ and the parameter N . The term “closed” will be explained in detail in Note 3.5 once we have proven our main result, Theorem 3.4. The method we use is the partial fraction decomposition. That is, consider the identity of Lemma 2.1 for $q = e^{i(\cdot, x)}$, $x \in \mathfrak{h}_{\mathbb{R}}$,

$$\sum_{N=0}^{\infty} z^N \text{Char } S^N V(\lambda)(ix) = \prod_{v \in X} \frac{1}{(1 - q^v z)^{m_\lambda(v)}}. \quad (7)$$

Partial fraction decomposition with respect to the variable z (abbreviated by PFD_z) of the right-hand side of Equation (7) gives

Proposition 3.1. *Let \mathfrak{g} be a semi-simple complex Lie algebra of rank r and $V(\lambda)$ a fixed irreducible representation of \mathfrak{g} with weight space decomposition $V(\lambda) = \bigoplus_{v \in X} V(\lambda)_v$ and weight multiplicity function $m_\lambda : X \rightarrow \mathbb{N}$. With $q = e^{i(\cdot, x)} = (q_1, \dots, q_r)$ as above,*

$$\text{PFD}_z \left(\prod_{v \in X} \frac{1}{(1 - q^v z)^{m_\lambda(v)}} \right) = \sum_{v \in X} \sum_{k=1}^{m_\lambda(v)} A_{v,k}(q) \frac{1}{(1 - q^v z)^k} \quad (8)$$

where for each $v \in X$ and $k \in \mathbb{N}$ we have $A_{v,k}(q) \in \mathbb{C}(q_1, \dots, q_r)$.

Proof. See e.g. Eustice and Klamkin (1979), Lang (2002), (Bliem, 2009, Lemma 1). \square

Note 3.2. The right-hand side of Equation (8) is a finite sum since the second summation gives zero if a weight v does not appear in $V(\lambda)$, i.e. $m_\lambda(v) = 0$.

We aim at a power series expansion of the right-hand side of Equation (8) with respect to the variable z . The following proposition will make life easier.

⁽ⁱ⁾ and on “Mickey Mouse”-analysis as Alan Huckleberry has put it to me in private communication

Proposition 3.3. For $v \in X$ and $q = e^{i(\cdot, x)}$ as above, we have

$$\frac{1}{(1 - q^v z)^k} = \sum_{N=0}^{\infty} z^N q^{Nv} p_k(N) \quad (9)$$

where $p_k(N)$ is a polynomial in N of degree $k-1$ given by $p_k(N) = \binom{N+k-1}{N}$.

Proof. Write down the Cauchy product of the k -th power of the geometric series $(1 - q^v z)^{-1}$. Then, you see that $p_k(N)$ is given by

$$p_k(N) = \sum_{j_{k-1}=0}^N \sum_{j_{k-2}=0}^{j_{k-1}} \cdots \sum_{j_1=0}^{j_2} 1 = \binom{N+k-1}{N}. \quad (10)$$

□

As a direct consequence of Equation (8) and Proposition 3.3 we obtain our main result.

Theorem 3.4 (Character formula). Let \mathfrak{g} be a semi-simple complex Lie algebra of rank r and $V(\lambda)$ a fixed irreducible representation of \mathfrak{g} with weight space decomposition $V(\lambda) = \bigoplus_{v \in X} V(\lambda)_v$ and weight multiplicity function $m_\lambda : X \rightarrow \mathbb{N}$. Then, with $q = e^{i(\cdot, x)} = (q_1, \dots, q_r)$ as above, we have

$$\text{Char } S^N V(\lambda)(ix) = \sum_{v \in X} q^{Nv} \sum_{k=1}^{m_\lambda(v)} A_{v,k}(q) \cdot p_k(N) \in \mathbb{C}(q_1, \dots, q_r)[X] \quad (11)$$

with rational functions $A_{v,k}(q) \in \mathbb{C}(q_1, \dots, q_r)$ and polynomials $p_k(N) \in \mathbb{Q}[N]$ of degree $k-1$ given by

$$p_k(N) = \binom{N+k-1}{N}. \quad (12)$$

Furthermore, for a weight $\mu \in X$ and $l = 0, \dots, m_\lambda(\mu) - 1$ we have

$$A_{\mu, m_\lambda(\mu)-l}(q) = \frac{(-1)^l}{l! q^{l\mu}} \cdot \frac{d^l}{(dz)^l} \left[\prod_{v \in X \setminus \mu} \frac{1}{(1 - q^v z)^{m_\lambda(v)}} \right]_{z=q^{-\mu}}. \quad (13)$$

Proof. From Equation (8) we see that

$$\text{Char } S^N V(\lambda)(ix) = \text{Res}_{z=0} \left[\frac{1}{z^{N+1}} \sum_{v \in X} \sum_{k=1}^{m_\lambda(v)} A_{v,k}(q) \frac{1}{(1 - q^v z)^k} \right]. \quad (14)$$

Then, Proposition 3.3 finishes the first part of the proof. For the second part multiply the right-hand side of Equation (8) by $(1 - q^\mu z)^{m_\lambda(\mu)}$ which is equivalent to take the product over $X \setminus \mu$ in Equation (13). By the product rule of differentiation we see that all summands except the μ -th one give zero after differentiation and evaluation at $q^{-\mu}$. Therefore, the remaining part is

$$\frac{d^l}{(dz)^l} \left[\sum_{k=1}^{m_\lambda(\mu)} A_{\mu,k}(q) (1 - q^\mu z)^{m_\lambda(\mu)-k} \right]_{z=q^{-\mu}} \quad (15)$$

$$\begin{aligned}
&= \left[\sum_{k=m_\lambda(\mu)-l}^{m_\lambda(\mu)} A_{\mu,k}(q) (-1)^l q^{l\mu} \prod_{i=0}^l (m_\lambda(\mu) - k - i) (1 - q^V z)^{m_\lambda(\mu) - k - l} \right]_{z=q^{-\mu}} \\
&= A_{\mu, m_\lambda(\mu)-l}(q) (-1)^l q^{l\mu} l!.
\end{aligned}$$

□

Note 3.5. Now we are able to explain the term “closed” used in the beginning of this section. Namely, the identity stated in Theorem 3.4 shows that all relevant data needed to describe the character of $S^N V(\lambda)$, in particular the rational functions $A_{\nu,k}(q)$, depends on the weight space decomposition and weight multiplicity function m_λ of the fixed representation $V(\lambda)$.

Note 3.6. Equation (13) might be a simple observation but it is a very effective method to compute the rational functions associated to weights of multiplicity 1. Then, we have no differentiation but just simple evaluation. In particular, one can immediately compute the character of the symmetric powers of a multiplicity free irreducible representation V . Note that in this case one could also obtain the character of $S^N V$ by plugging the k -many weights of the representation V into the complete homogeneous symmetric polynomial identity

$$h_N(x_1, \dots, x_k) = \sum_{i=1}^k \frac{x_i^N}{\prod_{j \neq i} (1 - x_j x_i^{-1})}. \quad (16)$$

As a consequence of Note 3.6 we can prove concrete character formulas for the symmetric powers of the irreducible representations $V(m)$ of \mathfrak{g} being of type A_1 and furthermore for the symmetric powers of the fundamental representation $V(\omega_1)$ of \mathfrak{g} of type A_r .

Corollary 3.7. For $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{C})$ and its irreducible representation $V(m)$, $m \in \mathbb{N}$, the Fourier series of the character of $S^N V(m)$ is given by

$$\text{Char } S^N V(m)(ix) = \sum_{i=0}^m q^{N(m-2i)} A_{m-2i,1}(q) \in \mathbb{C}(q)[X] \quad (17)$$

where $q = e^{ix}$ as above and with rational functions

$$A_{m-2i,1}(q) = (-1)^i q^{(m-i)(m-i+1)} \prod_{\substack{j=0 \\ j \neq i}}^m \frac{1}{q^{2|i-j|} - 1}. \quad (18)$$

Proof. The weights of $V(m)$ are given by $(m-2i)\omega_1$ where $i = 0, \dots, m$. By Theorem 3.4 we immediately obtain the claimed character formula and

$$\begin{aligned}
A_{m-2i,1}(q) &= \frac{(-1)^0}{0! q^{0(m-2i)\omega_1}} \frac{d^0}{(dz)^0} \left[\prod_{\substack{j=0 \\ j \neq i}}^m \frac{1}{1 - q^{(m-2j)} z} \right]_{z=q^{-(m-2i)}} = \prod_{\substack{j=0 \\ j \neq i}}^m \frac{1}{1 - q^{(m-2j)} q^{-(m-2i)}} \\
&= \prod_{0 \leq j < i} \frac{1}{1 - q^{2(i-j)}} \prod_{i < j \leq m} \frac{q^{2(j-i)}}{q^{2(j-i)} - 1} = (-1)^i q^{(m-i)(m-i+1)} \prod_{\substack{j=0 \\ j \neq i}}^m \frac{1}{q^{2|i-j|} - 1}.
\end{aligned} \quad (19)$$

□

Example 3.8. Let $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{C})$. Since $S^N V(0) = V(0)$ and $S^N V(1) = V(N)$, the first non-trivial example is given by the adjoint representation $V(2)$ and its symmetric powers $S^N V(2)$. By Corollary 3.7 we have

$$\text{Char } S^N V(2)(ix) = \frac{q^6}{(q^4 - 1)(q^2 - 1)} \cdot q^{2N} + \frac{-q^2}{(q^2 - 1)^2} \cdot q^0 + \frac{1}{(q^4 - 1)(q^2 - 1)} \cdot q^{-2N}. \quad (20)$$

Corollary 3.9. Let $\mathfrak{g} = \mathfrak{sl}(r+1, \mathbb{C})$ and consider its fundamental representation $V(\omega_1)$. Set $\omega_0 = \omega_{r+1} = 0$, i.e. extend $q = e^{i\langle \cdot, x \rangle} = (q_1, \dots, q_r)$ by $q_0 = q_{r+1} = 1$. Then,

$$\text{Char } S^N V(\omega_1)(ix) = \sum_{i=0}^r q_i^{-N} q_{i+1}^N A_{-\omega_i + \omega_{i+1}, 1}(q) \in \mathbb{C}(q_1, \dots, q_r)[X] \quad (21)$$

with rational functions

$$A_{-\omega_i + \omega_{i+1}, 1}(q) = q_{i+1}^r \prod_{\substack{j=0 \\ j \neq i}}^r \frac{q_j}{q_j q_{i+1} - q_{j+1} q_i}. \quad (22)$$

Proof. The weights of the fundamental representation $V(\omega_1)$ are $\omega_1, -\omega_1 + \omega_2, \dots, -\omega_{n-1} + \omega_n, -\omega_n$ all of multiplicity 1. Again, by Theorem 3.4 the claimed character formula follows and

$$\begin{aligned} A_{-\omega_i + \omega_{i+1}, 1}(q) &= \frac{(-1)^0}{0! q^{0(-\omega_i + \omega_{i+1})}} \frac{d^0}{(dz)^0} \left[\prod_{\substack{j=0 \\ j \neq i}}^r \frac{1}{1 - q_j^{-1} q_{j+1} z} \right]_{z=q_i q_{i+1}^{-1}} = \prod_{\substack{j=0 \\ j \neq i}}^r \frac{1}{1 - q_j^{-1} q_{j+1} q_i q_{i+1}^{-1}} \\ &= \prod_{\substack{j=0 \\ j \neq i}}^r \frac{q_j q_{i+1}}{q_j q_{i+1} - q_{j+1} q_i} = q_{i+1}^r \prod_{\substack{j=0 \\ j \neq i}}^r \frac{q_j}{q_j q_{i+1} - q_{j+1} q_i}. \end{aligned} \quad (23)$$

□

Remark 3.10. For $\mathfrak{g} = \mathfrak{sl}(r+1, \mathbb{C})$ we have an interesting aspect coming up. Since $S^N V(\omega_1) = V(N\omega_1)$, it is interesting to ask how the formulas obtained in Corollary 3.9 compare to the asymptotic theory of the Duistermaat-Heckman measure with respect to the sequence of representations $V(N\omega_1)$.

Note 3.11. Similarly to Corollary 3.9 one can compute the characters of the symmetric powers of the representations $V(\omega_i)$ for $i = 2, \dots, r$. Note that although the number of weights contributing to $S^N V(\omega_1) = V(N\omega_1)$ grows with N , their multiplicities always remain equal to 1. Nevertheless, the rational functions associated to $V(\omega_1)$ do not carry only trivial information, the number 1, but also encode which weights appear in $S^N V(\omega_1)$. In contrast, the weight multiplicities in $S^N V(\omega_i)$ for $i = 2, \dots, r$ are non-trivial and consequently their associated rational functions encode much more information. It is part of the full version of this extended abstract to compute the characters of the $S^N V(\omega_i)$ and compare those formulas.

For representations with higher dimensional weight spaces ($\dim \geq 2$) the computations become more difficult. We will demonstrate this by an example.

Example 3.12. Let $\mathfrak{g} = \mathfrak{sl}(3, \mathbb{C})$ and $V(\omega_1 + \omega_2)$ be its adjoint representation which decomposes as shown in the following picture, where $q = e^{i\langle \cdot, x \rangle} = (q_1, q_2) = (a, b)$ with respect to the fundamental weights ω_1, ω_2 and the simple coroots $\alpha_1^\vee, \alpha_2^\vee$.

The picture shows the Littelmann paths $\mathcal{P}_{\omega_1+\omega_2}$ of shape $\omega_1 + \omega_2$ (see e.g. Littelmann (1994)) and the elements of $\mathbb{Z}[a^{\pm 1}, b^{\pm 1}]$ corresponding to the weights of $V(\omega_1 + \omega_2)$. Here the difficulty lies in computing the rational function associated to the zero weight which has multiplicity 2. This is a first example of a non-trivial polynomial $p_k(N)$ coming up, namely $p_2(N) = N + 1$. We have

$$\begin{aligned} \text{Char } V(N\omega_1)(ix) = & (A_{0,1}(q) + A_{0,2}(q)p_2(N)) \cdot q^{N0} \\ & + A_{2\omega_1-\omega_2,1}(q) \cdot q^{N(2\omega_1-\omega_2)} + A_{-2\omega_1+\omega_2,1}(q) \cdot q^{N(-2\omega_1+\omega_2)} \\ & + A_{\omega_1-2\omega_2,1}(q) \cdot q^{N(\omega_1-2\omega_2)} + A_{-\omega_1+2\omega_2,1}(q) \cdot q^{N(-\omega_1+2\omega_2)} \\ & + A_{-\omega_1-\omega_2,1}(q) \cdot q^{N(-\omega_1-\omega_2)} + A_{\omega_1+\omega_2,1}(q) \cdot q^{N(\omega_1+\omega_2)}. \end{aligned} \quad (24)$$

The difficult part is

$$A_{0,1}(q) = \frac{d}{dz} \left[\prod_{v \in X \setminus \{0\}} \frac{1}{(1 - q^v z)^{m_{\omega_1+\omega_2}(v)}} \right]_{z=q^0=a^0b^0=1} = \frac{-3a^4b^4}{(ab-1)^2(a-b^2)^2(a^2-b)^2} \quad (25)$$

and we obtain

$$\begin{aligned} \text{Char } V(N\omega_1)(ix) = & \frac{-(3a^4b^4 + a^4b^4p_2(N))}{(ab-1)^2(a-b^2)^2(a^2-b)^2} \cdot a^0b^0 \\ & + \frac{a^{16}b}{(ab-1)(a-b^2)(a^2-b)^2(a^3-1)(a^3-b^3)(a^4-b^2)} \cdot a^{2N}b^{-N} \\ & + \frac{-b^9}{(ab-1)(a-b^2)(a^2-b)^2(a^3-1)(a^3-b^3)(a^4-b^2)} \cdot a^{-2N}b^N \\ & + \frac{a^9}{(ab-1)(a-b^2)^2(a^2-b)(b^3-1)(a^3-b^3)(a^2-b^4)} \cdot a^Nb^{-2N} \\ & + \frac{-ab^{16}}{(ab-1)(a-b^2)^2(a^2-b)(b^3-1)(a^3-b^3)(a^2-b^4)} \cdot a^{-N}b^{2N} \\ & + \frac{ab}{(ab-1)^2(a-b^2)(a^2-b)(b^3-1)(a^3-1)(a^2b^2-1)} \cdot a^{-N}b^{-N} \\ & + \frac{-a^9b^9}{(ab-1)^2(a-b^2)(a^2-b)(b^3-1)(a^3-1)(a^2b^2-1)} \cdot a^Nb^N. \end{aligned} \quad (26)$$

Let us end this section with an important note.

Note 3.13. In the notation of Theorem 3.4 note that iterated partial fraction decomposition with respect to the variables q_1, \dots, q_r gives the Fourier series associated to the character of $S^N V(\lambda)$. Thus, decomposing the character formula in Theorem 3.4 further with respect to q_1, \dots, q_r yields the weight multiplicity functions $m_{\lambda, N}$. We illustrate this by elaborating on Example 3.8 where $r = 1$. That is, let us decompose the character

$$\text{Char } S^N V(2)(ix) = \frac{q^6}{(q^4 - 1)(q^2 - 1)} \cdot q^{2N} + \frac{-q^2}{(q^2 - 1)^2} \cdot q^0 + \frac{1}{(q^4 - 1)(q^2 - 1)} \cdot q^{-2N} \quad (27)$$

further with respect to q . For e.g. $N = 0, \dots, 5$ this gives

N	$\text{Char } S^N V(2)(ix)$
1	$q^2 + 1 + q^{-2}$
2	$q^4 + q^2 + 2 + q^{-2} + q^{-4}$
3	$q^6 + q^4 + 2q^2 + 2 + 2q^{-2} + q^{-4} + q^{-6}$
4	$q^8 + q^6 + 2q^4 + 2q^2 + 3 + 2q^{-2} + 2q^{-4} + q^{-6} + q^{-8}$
5	$q^{10} + q^8 + 2q^6 + 2q^4 + 3q^2 + 3 + 3q^{-2} + 2q^{-4} + 2q^{-6} + q^{-8} + q^{-10}$.

4 A residue-type generating function for the weight multiplicities

Consider the Fourier series associated to the character of the representation $S^N V(\lambda)$ of our Lie algebra \mathfrak{g} , i.e. $\text{Char } S^N V(\lambda)(ix) = \sum_{\mathbf{v} \in X} m_{\lambda, N}(\mathbf{v}) e^{i\langle \mathbf{v}, x \rangle}$. Here $m_{\lambda, N}$ denotes the weight multiplicity function of $S^N V(\lambda)$. Then, by inverse Fourier transform we can recover the Fourier coefficients $m_{\lambda, N}(\mathbf{v})$ as

$$m_{\lambda, N}(\mathbf{v}) = \frac{1}{(2\pi)^r} \int_{\mathfrak{h}_{\mathbb{R}}/2\pi X^*} e^{-i\langle \mathbf{v}, x \rangle} \text{Char } S^N V(\lambda)(ix) dx. \quad (28)$$

Here dx is Lebesgue measure on $\mathfrak{h}_{\mathbb{R}}$ normalized such that the volume of the torus $T^r = \mathfrak{h}_{\mathbb{R}}/2\pi X^*$ is $(2\pi)^r$. Note that r is the rank of \mathfrak{g} . This yields the generating function for the weight multiplicity functions $m_{\lambda, N}$ evaluated at a specific weight. That is,

Proposition 4.1. *Let \mathfrak{g} be a semi-simple complex Lie algebra of rank r and $V(\lambda)$ a fixed irreducible representation of \mathfrak{g} . Let $m_{\lambda, N}$ be the weight multiplicity function of the N -th symmetric power $S^N V(\lambda)$. Let $\mu \in X$ be a fixed weight. Then, the formal power series $\sum_{N=0}^{\infty} z^N m_{\lambda, N}(\mu)$ is a holomorphic function in the variable z on $|z| \leq R < 1$. Moreover, we have the identity*

$$\sum_{N=0}^{\infty} z^N m_{\lambda, N}(\mu) = \frac{1}{(2\pi)^r} \int_{T^r} e^{-i\langle \mu, x \rangle} \prod_{\mathbf{v} \in X} \frac{1}{(1 - e^{i\langle \mathbf{v}, x \rangle} z)^{m_{\lambda, 1}(\mathbf{v})}} dx. \quad (29)$$

Proof. The assertion follows from the fact that the dimension of the symmetric power of a representation grows sub-exponentially in N as

$$\dim S^N V(\lambda) = \binom{\dim V(\lambda) - 1 + N}{N}. \quad (30)$$

This amounts to say that for the fixed weight $\mu \in X$ the power series $\sum_{N=0}^{\infty} z^N e^{-i\langle \mu, x \rangle} \text{Char} S^N V(\lambda)(ix)$ converges absolutely on $|z| \leq R < 1$ uniformly in $x \in T^r$. Namely, for arbitrary such x we have

$$\begin{aligned} |e^{-i\langle \mu, x \rangle} \text{Char} S^N V(\lambda)(ix)| &= \left| \sum_{\nu \in X} m_{\lambda, N}(\nu) e^{i\langle \nu, x \rangle} \right| \\ &\stackrel{(\text{triangle inequality})}{\leq} \sum_{\nu \in X} m_{\lambda, N}(\nu) \\ &= \binom{\dim V(\lambda) - 1 + N}{N} \\ &\stackrel{(\text{C some constant})}{=} CN^{\dim V(\lambda) - 1} + \text{lower terms}. \end{aligned} \quad (31)$$

Therefore the radius of convergence is given by

$$r = \frac{1}{\limsup_{N \rightarrow \infty} \sqrt[N]{|e^{-i\langle \mu, x \rangle} \text{Char} S^N V(\lambda)(ix)|}} = \frac{1}{\limsup_{N \rightarrow \infty} \sqrt[N]{|CN^{\dim V(\lambda) - 1} + \text{lower terms}|}} = 1. \quad (32)$$

By Lemma 2.1 the right-hand side of Equation (29) equals

$$\frac{1}{(2\pi)^r} \int_{T^r} e^{-i\langle \mu, x \rangle} \sum_{N=0}^{\infty} z^N \text{Char} S^N V(\lambda)(ix) dx \quad (33)$$

and since the previous convergence arguments allow us to integrate term by term, this finishes the proof. \square

Now we are able to explain why the generating function in Equation (29) is of residue-type.

Corollary 4.2 (Residue-type). *Let \mathfrak{g} be a semi-simple complex Lie algebra of rank r and $V(\lambda)$ a fixed irreducible representation of \mathfrak{g} . Let $m_{\lambda, N}$ be the weight multiplicity function of the N -th symmetric power $S^N V(\lambda)$. Let $\mu \in X$ be a fixed weight and denote $q^\mu = e^{i\langle \mu, x \rangle}$ as above. Then,*

$$m_{\lambda, N}(\mu) = \frac{1}{(2\pi)^r} \int_{T^r} q^{-\mu} \sum_{\nu \in X} q^{N\nu} \sum_{k=1}^{m_\lambda(\nu)} A_{\nu, k}(q) \cdot p_k(N) dx. \quad (34)$$

In particular, the multiplicity $m_{\lambda, N}(\mu)$ equals the constant term of the function $\text{Char} S^N V(\lambda)(ix)$ shifted by $q^{-\mu}$.

Proof. This is a direct consequence of Proposition 4.1 and Theorem 3.4. \square

Example 4.3. In the case $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{C})$ and the symmetric powers $S^N V(2)$ of the adjoint representation we have described in Note 3.13 that, e.g. for $N = 4$,

$$\text{Char} S^4 V(2)(ix) = q^8 + q^6 + 2q^4 + 2q^2 + 3 + 2q^{-2} + 2q^{-4} + q^{-6} + q^{-8}. \quad (35)$$

Note that $q = e^{ix}$. Now, in view of Corollary 4.2, the multiplicity of the weight $\mu = 2\omega_1$ in $S^4 V(2)$ is given by

$$m_{\lambda, N}(\mu) = m_{2, 4}(2) = \frac{1}{2\pi} \int_{S^1} q^{-2} (q^8 + q^6 + 2q^4 + 2q^2 + 3 + 2q^{-2} + 2q^{-4} + q^{-6} + q^{-8}) dx \quad (36)$$

$$= \frac{1}{2\pi} \int_{S^1} q^6 + q^4 + 2q^2 + 2q^0 + 3q^{-2} + 2q^{-4} + 2q^{-6} + q^{-8} + q^{-10} dx = \frac{1}{2\pi} \int_{S^1} 2q^0 dx = 2$$

Remark 4.4. Similar to Proposition 4.1 we have a generating function for the weight multiplicity functions $m_{\lambda,N}^\Lambda$ of the exterior powers $\Lambda^N V(\lambda)$ of an irreducible representation $V(\lambda)$. First, realize (see (Procesi, 2007, Chapter 9, §4.3)) that the graded character of the exterior algebra of $V(\lambda)$ is given by

$$\text{Char} \Lambda V(\lambda) = \sum_{N=0}^{\infty} z^N \text{Char} \Lambda^N V(\lambda) = \prod_{v \in X} (1 + e^v z)^{m_{\lambda,1}^\Lambda(v)}. \quad (37)$$

Then, again by inverse Fourier transform and the same convergence arguments we obtain a generating function with radius of convergence equal to 1, satisfying the identity

$$\sum_{N=0}^{\infty} z^N m_{\lambda,N}^\Lambda(\mu) = \frac{1}{(2\pi)^r} \int_{T^r} e^{-i\langle \mu, x \rangle} \prod_{v \in X} (1 + e^{i\langle v, x \rangle} z)^{m_{\lambda,1}^\Lambda(v)} dx. \quad (38)$$

Remark 4.5. For the tensor powers $T^N V(\lambda)$ of a fixed irreducible representation $V(\lambda)$ with weight multiplicity functions $m_{\lambda,N}^T$ we have the identity $\text{Char} T^N V(\lambda) = (\text{Char} V(\lambda))^N$ and consequently

$$(2\pi)^r \sum_{N=0}^{\infty} z^N m_N^T(\mu) = \int_{T^r} e^{-i\langle \mu, x \rangle} \sum_{N=0}^{\infty} z^N \text{Char} T^N V(\lambda)(ix) dx = \int_{T^r} e^{-i\langle \mu, x \rangle} \frac{1}{1 - \text{Char} V(\lambda)(ix)z} dx. \quad (39)$$

This constitutes a holomorphic function with radius of convergence equal to $\frac{1}{\dim V(\lambda)}$.

5 Connection to vector partition functions

For an integral matrix $A \in \mathbb{Z}^{(m,d)}$ with $\ker(A) \cap \mathbb{R}_+^d = \{0\}$ we define the vector partition function $\phi_A : \mathbb{Z}^m \rightarrow \mathbb{N}$ by

$$\phi_A(b) = \#\{x \in \mathbb{N}^d : Ax = b\}. \quad (40)$$

Let c_1, \dots, c_d denote the columns of A and use multiexponent notation $z^b = z_1^{b_1} \dots z_m^{b_m}$, $b \in \mathbb{Z}^m$. Then, as stated in (Bliem, 2009, Equation (1)), on $\{z \in \mathbb{C}^m : |z^{c_k}| < 1 \text{ for } k = 1, \dots, d\}$ we have the identity

$$f_A(z) := \sum_{b \in \mathbb{Z}^m} \phi_A(b) z^b = \prod_{k=1}^d \frac{1}{1 - z^{c_k}} \quad (41)$$

and

$$\phi_A(b) = \text{const} \left[f_A(z) \cdot z^{-b} \right]. \quad (42)$$

Now, there is an obvious connection between the graded character of the symmetric algebra $SV(\lambda)$ of an irreducible representation $V(\lambda)$ of a complex semi-simple Lie algebra \mathfrak{g} and the theory of vector partition functions, which is given by Lemma 2.1. Namely, if \mathfrak{g} is of rank r , then one has a matrix $A \in \mathbb{Z}^{(r+1, \dim V(\lambda))}$ encoding the weights of $V(\lambda)$ in terms of the coordinate system given by the fundamental weights $\omega_1, \dots, \omega_r$. This information corresponds to the first r rows of each column of A . In addition to that, we have the $(r+1)$ -th row which associates to the grading given by z in Lemma 2.1. That is, our particular matrix A has the following properties

1. The last row of A equals $(1, \dots, 1)$. (grading)
2. The columns of A reflect the Weyl group action. (symmetry)
3. The columns of A appear with multiplicities. (multiplicity)

In contrast to the computational and algorithmic aspects of iterated partial fraction decomposition as proposed in Beck (2004) and continued e.g. in Bliem (2009) for “arbitrary” matrices A , our interests are different. They lie in investigating further the closed character formulas for the symmetric powers and the impact of the grading, symmetry and multiplicity properties of our matrix A on the iterated partial fraction decomposition. One aspect is described in detail in Section 6.

6 Weyl group orbits and the Main Theorem

In the notation of Theorem 3.4 write the character of $S^N V(\lambda)$ as the sum over the dominant weights and their Weyl group orbits, i.e.

$$\text{Char } S^N V(\lambda)(ix) = \sum_{\nu \in X^+} \sum_{w \in W/W_\nu} q^{Nw \cdot \nu} \sum_{k=1}^{m_\lambda(\nu)} A_{w \cdot \nu, k}(q) \cdot p_k(N). \quad (43)$$

Here W_ν denotes the stabilizer of the weight ν . Note that the multiplicity of a weight is invariant under the operation of the Weyl group (see e.g. (Carter, 2005, Proposition 10.22)). Now, for a fixed dominant weight $\nu \in X^+$ let

$$f_{\nu, N}(q) = \sum_{w \in W/W_\nu} q^{Nw \cdot \nu} \sum_{k=1}^{m_\lambda(\nu)} A_{w \cdot \nu, k}(q) \cdot p_k(N) \in \mathbb{C}(q_1, \dots, q_r)[X] \quad (44)$$

so that $\text{Char } S^N V(\lambda)(ix) = \sum_{\nu \in X^+} f_{\nu, N}(q)$. It is interesting to ask how the iterated partial fraction decomposition with respect to the variables q_1, \dots, q_r of a single summand $f_{\nu, N}(q)$ looks like. Examples indicate that this decomposition of $f_{\nu, N}(q)$ does not yield information about the weights outside the convex hull of the Weyl group orbit $W \cdot (N\nu)$. Furthermore, some additional terms appear which sum up to zero when taken over all dominant weights X^+ . We will illustrate this by an example in the case of \mathfrak{g} being of rank 1 to avoid confusing computations.

Example 6.1. Consider the sequence of representations $S^N V(3)$ of $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{C})$. Then, by Corollary 3.7 we have

$$\begin{aligned} \text{Char } S^N V(3)(ix) = & \frac{q^{12}}{(q^6 - 1)(q^4 - 1)(q^2 - 1)} \cdot q^{3N} + \frac{-q^6}{(q^4 - 1)(q^2 - 1)^2} \cdot q^N \\ & + \frac{q^2}{(q^4 - 1)(q^2 - 1)^2} \cdot q^{-N} + \frac{-1}{(q^6 - 1)(q^4 - 1)(q^2 - 1)} \cdot q^{-3N} \end{aligned} \quad (45)$$

where $q = e^{ix}$. Hence, following the notation introduced in Equation (44) we set

$$f_{1, N}(q) = \frac{-q^6}{(q^4 - 1)(q^2 - 1)^2} \cdot q^N + \frac{q^2}{(q^4 - 1)(q^2 - 1)^2} \cdot q^{-N} \quad (46)$$

$$f_{3,N}(q) = \frac{q^{12}}{(q^6-1)(q^4-1)(q^2-1)} \cdot q^{3N} + \frac{-1}{(q^6-1)(q^4-1)(q^2-1)} \cdot q^{-3N}. \quad (47)$$

Now, e.g. for $N = 4$, we obtain

$$\text{PFD}_q(f_{1,4}(q)) = -q^2 - 2 - q^{-2} - \frac{3}{4(q-1)^2} + \frac{3}{4(q+1)} - \frac{3}{4(q-1)} - \frac{3}{4(q+1)^2} \quad (48)$$

and

$$\begin{aligned} \text{PFD}_q(f_{3,4}(q)) = & q^{12} + q^{10} + 2q^8 + 3q^6 + 4q^4 + 5q^2 + 7 + 5q^{-2} + 4q^{-4} + 3^{-6} + 2q^{-8} \\ & + q^{-10} + q^{-12} + \frac{3}{4(q-1)^2} - \frac{3}{4(q+1)} + \frac{3}{4(q-1)} + \frac{3}{4(q+1)^2}, \end{aligned} \quad (49)$$

where in each individual decomposition the last four summands are the additional terms which sum up to zero. Unfortunately this example indicates that we cannot expect a positive formula for the weight multiplicities of the symmetric powers.

7 Acknowledgements

The author would like to thank the referees for their careful reviews and comments, and for pointing me to the identity in Note 3.6.
